

1  
2 **Submission to the Special Committee on COVID-19 Response**  
3 **on the topic of**  
4 **Covid-19 Testing and Contact Tracing**

5  
6  
7 Dr. Stephen Farrell and Prof. Doug Leith  
8 16<sup>th</sup> June 2020  
9

10  
11 We would like to thank the committee for the opportunity to make our submission on this  
12 topic. This is a joint submission by Prof. Doug Leith and Dr. Stephen Farrell, of the School  
13 of Computer Science and Statistics, Trinity College Dublin. Our submission relates only to  
14 technology issues with the planned HSE contact tracing "App" and to such Apps in  
15 general. Our expertise is in computer systems, security, privacy and networking and not in  
16 epidemiology. This submission reflects our personal views and not those of Trinity College  
17 Dublin.

18  
19 We have carried out independent analysis and tests of the technologies underlying  
20 COVID-19 contact tracing Apps, initially based on the open-source version of the  
21 Singapore "OpenTrace" App, and more recently based on the Google/Apple Exposure  
22 Notification (GAEN) system that will be used by the HSE App. We have not, at the time of  
23 writing, seen or done tests with the HSE's own App. We have published a number of  
24 results from this work at <https://down.dsg.cs.tcd.ie/tact> and have additional results we plan  
25 to publish in upcoming days. Our publications on this topic have not so far been peer-  
26 reviewed as we felt it important to make them available in a timely manner for the technical  
27 community including the developers of Apps such as the HSE's.

28  
29 We believe everyone with whom we have interacted on this topic has the best interests of  
30 Irish and other citizens at heart. That includes Civil society organisations, the HSE and  
31 their contractors, Google and Apple employees, and individual Irish-based and  
32 international experts and developers. We were assisted in gaining the authorisation  
33 required from Google and Apple to test the GAEN system thanks to HSE staff. Trinity  
34 College Dublin provided funds for us to acquire the handsets we used in testing.

35  
36 **Results and Recommendations**

37  
38 Our tests so far indicate that it will be challenging for any such App to be effective. For  
39 example a train carriage or bus provides a very difficult environment for such Apps, and  
40 how a person carries their phone has a major impact, but is impossible to control.

41  
42 The highest-level take-away is: **the HSE App might not be effective, but is worth**  
43 **trying, if, but only if, that attempt is made in the knowledge that it is an experiment**  
44 **that may not succeed.** Messaging to the public should reflect that likelihood. How to do  
45 such messaging is not within our area of expertise.  
46  
47

48 At one level down:

49

- 50 • If COVID-19 tracing Apps could materially improve contact tracing that would be  
51 beneficial. That requires that those Apps materially improve the overall contact  
52 tracing and testing system, so what will count is the added value of the App to that  
53 overall system. It is not clear at present if Apps will or will not provide such an  
54 improvement. When deploying a contact tracing app measures should therefore be  
55 put in place to collect data on the added value of the app within the larger contact  
56 tracing and testing system. Such measures will likely be as an addition to the  
57 interactions between contact tracing personnel and the public and not as a technical  
58 feature of the HSE App.
- 59 • It remains worthwhile expending effort to experiment with such Apps in Ireland, but  
60 that must be done with an awareness that there is a high probability the results will  
61 be negative or inconclusive. In other words - do keep trying, but do not depend on  
62 (or claim) inevitable success - inconclusive results or failure seem to us more likely  
63 at this point. There are also security and privacy risks inevitable when deploying  
64 these Apps, so there is also a need to ensure proportionality considering both the  
65 costs and benefits.

66

67 There are two high-level risks that may cause such Apps to be ineffective:

68

- 69 • Bluetooth Low-Energy (BLE) may not determine proximity with sufficient accuracy  
70 due to the vagaries of radio propagation in real-world environments and with how  
71 devices are carried. If so, that will be due to the laws of physics and not the failings  
72 of developers or those promoting the use of such Apps. As BLE proximity is  
73 complex and varies by handset, Google and Apple probably need to be part of the  
74 development of any credible solution, if a working solution exists, which is  
75 uncertain.
- 76 • Insufficient use. That can be caused in a variety of ways - in a fast changing  
77 environment, one cause for this risk is a lack of trust in various of the entities  
78 involved, including government, Google and Apple and the potential for future  
79 abuses of this technology for commercial purposes. In our opinion, people are  
80 justified being suspicious of Google and Apple when it comes to tracking, as mobile  
81 Apps of many kinds are widely known to track people pervasively. Awareness  
82 campaigns may thus be unable to address this risk. (We nonetheless believe  
83 Google and Apple are acting in good faith in this effort - such mistrust is just one of  
84 the costs of surveillance capitalism.)

85

86 We would also like to draw attention to some other aspects of such Apps that may not  
87 feature in other submissions:

88

- 89 • Further entrenching of the Google/Apple duopoly via socially-important functionality  
90 such as this is undesirable. A short-term emergency may make that acceptable, if it  
91 is clear that the emergency will be mitigated by the Apps. Today, that is not clear.
- 92 • If these Apps are deployed at scale, it is critical to devote as much effort and  
93 attention to undeployment at the end of the emergency, perhaps via legislation, so  
94 that the infrastructure is not re-purposed for commercial, or other, surveillance.
- 95 • Deploying such Apps may encourage others (employers, transport operators,  
96 stores) to require use of similar technologies, without the benefit of the kind of  
97 scrutiny being provided by this committee or by technologists worldwide. That could

98 badly infringe on various rights and freedoms. The HSE App is not the only relevant  
99 thing that could have security or privacy implications in this space, but the HSE App  
100 may set a local precedent that could be widely followed. Society might benefit if the  
101 committee revisit that topic as such systems are deployed by private entities in the  
102 coming months.

- 103 • It is good that the HSE have promised to publish their code. That is necessary and  
104 the sooner the better. The HSE should also publish the code used in their various  
105 backend systems and not only the code that runs on the mobile handset.
- 106 • The same is not so far true of the implementation of the Google/Apple systems  
107 which are a part of their mobile operating systems and remains closed source and  
108 with limited documentation. We would encourage the committee to request Google  
109 and Apple to open-source their implementations as well. Without that, Irish citizens  
110 will be vulnerable to potential errors made by Google or Apple developers.
- 111 • We have seen updates of the Google implementation pushed out while we tested.  
112 That is quite understandable, but shows Google or Apple could at any time affect  
113 the false positive/false negative rates of the HSE App with no control or oversight by  
114 the HSE, Irish government or the technology community.

### 115 **Bluetooth Low Energy Proximity**

116  
117  
118 Based on the tests we have conducted so far, we believe the first risk of inaccuracy in  
119 distance estimation is very significant. While accuracy can be demonstrated in tests in  
120 some laboratory conditions, our tests so far in more real-world scenarios [1] indicate that  
121 accuracy in a real deployment will be far more challenging. Follow-up work has continued  
122 to indicate that these challenges are real and hard to handle, for example the relative  
123 orientation of two devices (whether they are both top-up, or front-to-front) has a significant  
124 effect on the signal strength seen. Additionally, we have seen significant and large  
125 variations in received signal strengths when different models of device are tested under  
126 the exact same conditions. (We plan to publish these results shortly after this submission  
127 is due.)

128  
129 To explain the BLE proximity issue in more detail: BLE is a radio technology used in mobile  
130 handsets, for example, to connect handsets to headphones. BLE is intended for use with  
131 nearby devices, and so uses low power radio transmission. As radio waves propagate  
132 roughly spherically in all directions, the power of the transmission weakens over distance,  
133 as do the ripples or waves caused by a stone dropped into water. If you start by making a  
134 set of measurements with different sized stones and different distances and if you know  
135 the size of the stone and the size of the wave when it reaches you, you can estimate how  
136 far you might be from where the stone entered the water. However, if you do that in a bath,  
137 waves will bounce off the sides and make your estimation much less accurate. Or, if there  
138 is a body in the bath, that will affect your accuracy too. While no analogy is perfect, the  
139 same effects happen with BLE radio distance estimation - a phone upside down in a back  
140 pocket when sitting on a metal chair will be estimated to be much further away than one  
141 nicely oriented in a shirt pocket. One result is that a person 4 metres away in a train  
142 carriage can appear "closer" than one 2 metres away due to reflection of the radio waves  
143 off the metal carriage walls, floor and ceiling. It is unclear if even the engineers of Google  
144 and Apple and the HSE can cater for all these possibilities without generating many false  
145 negatives (where someone truly in proximity is missed) while keeping an acceptable level  
146 of false positives (where someone is mistakenly considered as having been in proximity).

148 For COVID-19 tracing Apps, the effect of a false negative is that someone who may be  
149 infected goes undetected and infects others. The effect of a false positive may be that  
150 someone needlessly isolates for two weeks.

151

## 152 **Privacy and Security**

153

154 The typical tools used by App developers for commercial Apps often include features to  
155 allow developers track how their Apps are being used. This can be, and often is, done in a  
156 manner that is extremely privacy invasive. For example, such that every time a person  
157 opens the App on their phone, that information is sent to a server located in some other  
158 country, typically in the United States or under the control of a company based there. We  
159 carried out an analysis of the Singapore App [2] that indicates that it suffers from such  
160 deficiencies. Open-sourcing the HSE App and associated back-end system will enable us  
161 and others to ensure that the HSE have done a good job in this respect. We do believe  
162 that is their intention but it is in fact easy to make mistakes in this respect and accidentally  
163 include trackers via relatively low-level use of libraries and other systems that are part of  
164 the commercial mobile App ecosystem.

165

166 Various well-known attacks exist against any of these systems, and using estimated Irish  
167 numbers, we have documented one method of attack [3] that could lead to approximately  
168 four false positives for every real positive whilst a COVID testing station was under attack.  
169 We consider the risk that someone attempts such an attack somewhere in the world is  
170 high. Once demonstrated, copy-cat attacks in other places such as Ireland would be likely  
171 and could damage confidence in the App sufficient to fatally affect utility. Preventing all  
172 such attacks is extremely hard and we are not aware of any proposal in this space that has  
173 no such vulnerability.

174

175 The underlying cause is the need for everyone's handset to accept broadcasts from  
176 anyone's handset without real-time strong authentication. This makes the problem roughly  
177 as hard as eradicating spam in email. Any system (centralised or not) that fully addressed  
178 these threats via strong authentication could require the equivalent of a major overhaul of  
179 the worldwide mobile ecosystem, which will not happen in the relevant time-frame.

180

## 181 **Undeployment**

182

183 Planned "undeployment" is an unusual thing for computer applications. As such, it will  
184 require additional analysis that we imagine is likely not a part of typical HSE or other  
185 development processes, especially when done under time-pressure as is the case here.  
186 As one example, the use of new Domain Name System (DNS) sub-domains for server  
187 names and the use of new code-signing certificates that can be revoked later may make  
188 undeployment easier, more thorough and more convincing, but only if plans are made for  
189 that now, before any real deployment. We understand that the HSE may have such plans  
190 in place, and those ought be published as soon as possible, even if in draft form.

191

## 192 **Summary**

193

194 We believe continued work on the HSE App is warranted, but all involved need to assume  
195 that a lack of demonstrated utility for contact tracing Apps is more likely than success. Do  
196 the work, roll it out, but without making unwarranted claims that the overall system will  
197 work, until that is in fact demonstrated by experience. Always be ready to stop and take

198 the App down from the App stores. And regardless of success or failure, make sure to  
199 ensure that all the infrastructure is dismantled as soon as possible.
